

Figure 7. Condition-level signal architectures

Descriptive organization of FSF regions across features within each condition

I. Highly Stable-dominated architecture e.g., HT, OSM, LT

● Highly Stable ● Low Stability

Highly Stable core

Highly Stable predominance defines a Highly Stable-dominated condition-level signal architecture.

- Highly Stable region predominates
- HT and OSM are uniformly Highly Stable
- LT retains a small Low Stability component

II. Two-region architecture e.g., DES

● Highly Stable ● Low Stability

Coexisting regions

DES combines Highly Stable and Low Stability regions in a two-region architecture.

- Highly Stable and Low Stability coexist
- DES: 61.6% Highly Stable, 38.4% Low Stability
- No Stable or Transitional component

III. Multi-layer architecture e.g., UV, GAM

● Highly Stable ● Stable ● Transitional ● Low Stability

Multiple FSF layers

Coexisting FSF regions generate more compositionally heterogeneous architectures.

- Multiple FSF regions coexist
- GAM: Stable largest
- UV: Transitional-dominant
- Higher compositional heterogeneity

DESCRIPTIVE INTERPRETATION

What the architectures show

Highly Stable-dominated

- Highly Stable region predominates
- Lower compositional heterogeneity
- HT and OSM are uniform; LT retains minor Low Stability

Two-region architecture

- Highly Stable + Low Stability
- DES: 61.6% / 38.4%
- Structural description only

Multi-layer architecture

- Multiple FSF regions coexist
- GAM: Stable largest; UV: Transitional-dominant
- Higher compositional heterogeneity

FSF region color key

● Highly Stable

● Stable

● Transitional

● Low Stability

Each circle represents the FSF region assigned to a feature in a condition based on SSI and dominant state.

FSF links feature-level signal identity to distinct condition-level signal architectures and supports descriptive interpretation without causal, adaptive, fitness, or mechanistic inference.
